# Scientific Programming Practical 6

Introduction

#### **Exercises**

- 1. Given the following two lists of integers: [1, 13, 22, 7, 43, 81, 77, 12, 15,21, 84,100] and [44,32,7, 100, 81, 13, 1, 21, 71]:
  - 1. Sort the two lists
  - Create a third list as intersection of the two lists (i.e. an element is in the intersection if it is present in both lists).
  - 3. Print the three lists.

```
"""First solution, prints multiple times repeated elements in L1"""
L1 = [1, 13, 22, 7, 43, 81, 77, 12, 15, 21, 84, 100]
L2 = [44,32,7,100,81,13,1,21,71]
L1.sort()
L2.sort()
intersection = [x for x in L1 if x in L2]
print("L1: ", L1)
print("L2: ", L2)
print("inters:", intersection)
L1 = [1, 9, 1, 7, 44, 9, 9, 9, 81, 77, 12, 15, 21, 84, 100]
L2 = [44, 32, 21, 7, 100, 81, 13, 9, 1, 21, 71]
print("\n-----")
L1.sort()
L2.sort()
intersection = [x for x in L1 if x in L2]
print("L1: ", L1)
print("L2: ", L2)
print("inters:", intersection)
print("\n\n -----")
"""Second solution, does not print multiple times repeated elements in L1"""
print("L1: ", L1)

```

A function is a block of code that has a name and that performs a task.

A function can be thought of as a **box** (even as a black box: e.g. print()) that gets an **input** and returns an **output** (**or None**).

```
The basic definition of a function is:

def function_name(input) :
    #code implementing the function
    ...
    return return_value
```

- 1. **Reduce code duplication**: put in functions parts of code that are needed several times in the whole program so that you don't need to repeat the same code over and over again;
- 2. **Decompose a complex task**: make the code easier to write and understand by splitting the whole program into several easier functions

```
import math
X = [1, 5, 4, 4, 7, 2, 1]
Y = [9, 4, 7, 1, 2]
Z = [9, 9, 4, 7]
sum x = 0
sum y = 0
sum z = 0
                                           duplicated code
for el in X:
    sum x += math.sqrt(el)
for el in Y:
    sum y += math.sqrt(el)
for el in Z:
    sum z += math.sqrt(el)
print(X, "sum sqrt:", sum x)
print(Y, "sum sqrt:", sum y)
print(Z, "sum sqrt:", sum z)
```

```
[1, 5, 4, 4, 7, 2, 1] sum_sqrt: 12.296032850937475
[9, 4, 7, 1, 2] sum_sqrt: 10.059964873437686
[9, 9, 4, 7] sum sqrt: 10.64575131106459
```

```
import math
X = [1, 5, 4, 4, 7, 2, 1]
Y = [9, 4, 7, 1, 2]
Z = [9, 9, 4, 7]
# This function does not return anything
def print sum sqrt(vals):
    tmp = 0
    for el in vals:
        tmp += math.sqrt(el)
    print(vals, "sum sqrt:", tmp)
print sum sqrt(X)
print sum sqrt(Y)
print sum sqrt(Z)
[1, 5, 4, 4, 7, 2, 1] sum sqrt: 12.296032850937475
[9, 4, 7, 1, 2] sum sqrt: 10.059964873437686
[9, 9, 4, 7] sum sqrt: 10.64575131106459
```

```
import math
X = [1, 5, 4, 4, 7, 2, 1]
Y = [9, 4, 7, 1, 2]
Z = [9, 9, 4, 7]
sum x = 0
sum y = 0
sum z = 0
                                           duplicated code
for el in X:
    sum x += math.sqrt(el)
for el in Y:
    sum y += math.sqrt(el)
for el in Z:
    sum z += math.sqrt(el)
print(X, "sum sqrt:", sum x)
print(Y, "sum sqrt:", sum y)
print(Z, "sum sqrt:", sum z)
```

```
[1, 5, 4, 4, 7, 2, 1] sum_sqrt: 12.296032850937475
[9, 4, 7, 1, 2] sum_sqrt: 10.059964873437686
[9, 9, 4, 7] sum_sqrt: 10.64575131106459
```

#### Another function returning the sum

```
import math
X = [1, 5, 4, 4, 7, 2, 1]
Y = [9, 4, 7, 1, 2]
Z = [9, 9, 4, 7]
# This function returns the sum
def sum sqrt(vals):
    tmp = 0
    for el in vals:
        tmp += math.sqrt(el)
    return tmp
x = sum sqrt(X)
y = sum sqrt(Y)
z = sum sqrt(Z)
print(X, "sum sqrt:", x)
print(Y, "sum sqrt:", y)
print(Z, "sum sqrt:", z)
# we have the sums as numbers, can use them
print("Sum of all: ", x + y + z)
[1, 5, 4, 4, 7, 2, 1] sum sqrt: 12.296032850937475
[9, 4, 7, 1, 2] sum sqrt: 10.059964873437686
[9, 9, 4, 7] sum sqrt: 10.64575131106459
Sum of all: 33.00174903543975
```

**Example:** Let's write a function that, given a list of elements, prints only the even-placed ones without returning anything.

This is a polymorphic function (i.e. it works on several data types, provided that we can iterate through them)!

```
def get even placed(myList):
    """returns the even placed elements of myList"""
    ret = [myList[i] for i in range(len(myList)) if i % 2 == 0]
    print(ret)
L1 = ["hi", "there", "from", "python", "!"]
L2 = list(range(13))
print("L1:", L1)
print("L2:", L2)
print("even L1:")
get even placed(L1)
print("even L2:")
get even placed(L2)
L1: ['hi', 'there', 'from', 'python', '!']
L2: [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12]
even L1:
['hi', 'from', '!']
even L2:
[0, 2, 4, 6, 8, 10, 12]
```

# Namespaces and scope

**Namespaces** are mappings from *names* to objects, or in other words <u>places (i.e.</u> <u>dictionaries)</u> where names are associated <u>to objects.</u>

Namespaces can be considered as the context.

According to Python's reference a **scope** is a *textual region of a Python program,* where a namespace is directly accessible

```
    **Local**: the innermost that contains local names (inside a function or a class);
    **Enclosing**: the scope of the enclosing function, it does not contain local nor global names (nested functions);
    **Global**: contains the global names;
    **Built-in**: contains all built in names (e.g. print, if, while, for,...)
```

**LEGB** order for finding variable

# Namespace and scope

```
    **Local**: the innermost that contains local names (inside a function or a class);
    **Enclosing**: the scope of the enclosing function, it does not contain local nor global names (nested functions);
    **Global**: contains the global names;
    **Built-in**: contains all built in names (e.g. print, if, while, for,...)
```

```
var = 'global'
var2 = 'global'
def my f():
    var = 'enclosing'
    var2 = 'enclosing'
    def my inner f():
        var = 'local'
        print("\t\t\tvar:", var)
        print("\t\t\tvar2:", var2)
    print("\t\tcalling my inner f:")
    my inner f()
    print("\tvar", var)
    print("\tvar2", var2)
print("var:", var)
print("var2:", var2)
print("\tcalling my f:")
my f()
print("var:", var)
print("var2:", var2)
var: global
var2: global
        calling my f:
                calling my inner f:
                        var: local
                        var2: enclosing
        var enclosing
        var2 enclosing
var: global
var2: global
```

**Example:** define a function that gets a list of integers and returns its sum.

Importantly enough, a function needs to be defined (i.e. its code has to be written) BEFORE it can actually be used.

```
A = [1, 2, 3]
my sum(A)
def my_sum(myList):
    ret = 0
    for el in myList:
        ret += el
    return ret
NameError
                                           Traceback (most recent call last)
<ipython-input-7-585169a2991a> in <module>()
      1 A = [1,2,3]
----> 2 my_sum(A)
      4 def my sum(myList):
            ret = 0
NameError: name 'my sum' is not defined
```

# Argument passing

Things to remember

- 1. Passing an argument is actually assigning an object to a local variable name;
- 2. Assigning an object to a variable name within a function does not affect the caller;
- 3. Changing a mutable object variable name within a function affects the caller

# Argument passing

- 1. Passing an argument is actually assigning an object to a local variable name;
- 2. Assigning an object to a variable name within a function does not affect the caller;
- Changing a mutable object variable name within a function affects the caller

```
"""Assigning the argument does not affect the caller"""

def my_f(x):
    x = "local value" #local
    print("Local: ", x)

x = "global value" #global
my_f(x)
print("Global:", x)
my_f(x)

Local: local value
Global: global value
Local: local value
```

# Argument passing

- 1. Passing an argument is actually assigning an object to a local variable name;
- 2. Assigning an object to a variable name within a function does not affect the caller;
- 3. Changing a mutable object variable name within a function affects the caller

```
"""Changing a mutable affects the caller"""

def my_f(myList):
    myList[1] = "new value1"
    myList[3] = "new value2"
    print("Local: ", myList)

myList = ["old value"]*4
print("Global:", myList)
my_f(myList)
print("Global now: ", myList)

Global: ['old value', 'old value', 'old value', 'old value']
Local: ['old value', 'new value1', 'old value', 'new value2']
Global now: ['old value', 'new value1', 'old value', 'new value2']
```

**Example:** Let's write a function that, given a list of integers, returns the number of elements, the maximum and minimum.

We need to make a copy if we want to modify a mutable within a function without affecting the orginal object

```
"""easy! this changes the original list!!!"""
def get info(myList):
    """returns len of myList, min and max value
    (assumes elements are integers) but it would work with str""
    myList.sort()
    return len(myList), myList[0], myList[-1] #return type is a tuple
A = [7, 1, 125, 4, -1, 0]
print("Original A:", A, "\n")
result = get info(A)
print("Len:", result[0], "Min:", result[1], "Max:", result[2], "\n" )
print("A now:", A)
Original A: [7, 1, 125, 4, -1, 0]
Len: 6 Min: -1 Max: 125
A now: [-1, 0, 1, 4, 7, 125]
```

**Example:** Let's write a function that, given a list of integers, returns the number of elements, the maximum and minimum.

We need to make a copy if we want to modify a mutable within a function without affecting the orginal object

```
def get info(myList):
    """returns len of myList, min and max value
    (assumes elements are integers) but it would work with str"""
    tmp = myList[:] #copy the input list
    tmp.sort()
    return len(tmp), tmp[0], tmp[-1] #return type is a tuple
A = [7, 1, 125, 4, -1, 0]
print("Original A:", A, "\n")
result = qet info(A)
print("Len:", result[0], "Min:", result[1], "Max:", result[2], "\n" )
print("A now:", A)
Original A: [7, 1, 125, 4, -1, 0]
Len: 6 Min: -1 Max: 125
A now: [7, 1, 125, 4, -1, 0]
```

**Example**. Write a function that rounds a float at a precision (i.e. number of decimals) specified in input. If no precision is specified then the whole number should be returned. Examples:

```
my_round(1.1717413, 3) = 1.172
my_round(1.1717413, 1) = 1.2
my_round(1.1717413) = 1.1717413
```

```
import math
def my round(val, precision = 0):
    if precision == 0:
        return val
    else:
        return round(val * 10** precision)/ 10**precision
my val = 1.717413
print(my val, " precision 2: ", my round(my val,2))
print(my val, " precision 1: ", my round(my val,1))
print(my val, " precision max: ", my round(my val))
print("")
my val = math.pi
print(my val, " precision 10: ", my round(my val,10))
1.717413 precision 2: 1.72
1.717413 precision 1: 1.7
1.717413 precision max: 1.717413
3.141592653589793 precision 10: 3.1415926536
```

Let's create now a list with the square root values of the first 20 integers with 3 digits of precision.

#### **Functions**

import math

def my\_round(val, precision = 0):
 if precision == 0:
 return val
 else:
 return round(val \* 10\*\* precision)/ 10\*\*precision

result = [my\_round(math.sqrt(x), 3) for x in range(1,21)]

print(result)
[1.0, 1.414, 1.732, 2.0, 2.236, 2.449, 2.646, 2.828, 3.0, 3.162, 3.317, 3.464, 3.606, 3.742, 3.873, 4.0, 4.123, 4.243, 4.359, 4.472]

we can apply functions in a list comprehension...

Another example... with and without list comprehension

Let's print only the values of the list result above whose digits sum up to a certain value x. Hint: write another function!

```
import math
def my round(val, precision = 0):
    if precision == 0:
        return val
    else:
        return round(val * 10** precision)/ 10**precision
#version without list comprehension
def sum of digits noList(num, total):
    tmp = str(num)
    tot = 0
    for d in tmp:
        if d != ".":
            tot += int(d)
   if tot == total:
        return True
    else:
        return False
#with list comprehension
def sum of digits(num, total):
    tmp = [int(x) for x in str(num) if x != "."]
    return sum(tmp) == total
result = [my round(math.sqrt(x), 3) for x in range(1,21)]
print("sum is 10:", [x for x in result if sum of digits(x, 10)])
print("sum is 13:",[x for x in result if sum of digits(x, 13)])
sum is 10: [1.414, 4.123]
sum is 13: [1.732, 2.236, 4.243]
```

# Argument passing by keyword and defaults

We can specify default values (that can be overridden) and name the parameters of a function...

```
def print parameters(a="defaultA", b="defaultB",c="defaultC"):
    print("a:",a)
    print("b:",b)
    print("c:",c)
print parameters("param A")
print("\n###########\n")
print parameters(b="PARAMETER B")
print("\n##########\n")
print parameters()
print("\n##########\n")
print parameters(c="PARAMETER C", b="PAR B")
a: param A
b: defaultB
c: defaultC
###################
a: defaultA
b: PARAMETER B
c: defaultC
###################
a: defaultA
b: defaultB
c: defaultC
#################
a: defaultA
b: PAR B
c: PARAMETER C
```

# String formatting

```
#simple empty placeholders
print("I like {} more than {}.\n".format("python", "java"))
#indexed placeholders, note order
print("I like {0} more than {1} or {2}.\n".format("python", "java", "C++"))
print("I like {2} more than {1} or {0}.\n".format("python", "java", "C++"))
#indexed and named placeholders
print("I like {1} more than {c} or {0}.\n".format("python", "java", c="C++"))
#with type specification
import math
print("The square root of {0} is {1:f}.\n".format(2, math.sqrt(2)))
#with type and format specification (NOTE: {.2f})
print("The square root of {0} is {1:.2f}.\n".format(2, math.sqrt(2)))
#spacing data properly
print("{:2s}|{:5}|{:6}".format("N", "sqrt", "square"))
for i in range (0,20):
    print("{:2d}|{:5.3f}|{:6d}".format(i,math.sgrt(i),i*i))
```

Format can be used to add values to a string in specific placeholders (normally defined with the syntax {}) or to format values according to the user specifications (e.g. number of decimal places for floating point numbers).

More info https://docs.python.org/3/library/string.html#format-string-syntax

# File Input/Output

#### In the next practical!

With files you need to perform 3 steps:

Open the file, read/write, close

	Built-in function	Meaning
file	open(str, [str])	Get a handle to a file

Result	Method	Meaning
str	file.read()	Read all the file as a single string
list of str	file.readlines()	Read all lines of the file as a list of strings
str	file.readline()	Read one line of the file as a string
None	file.write(str)	Write one string to the file
None	file.close()	Close the file (i.e. flushes changes to disk)

# File Input/Output

With files you need to:

Open, read/write, close

Opening mode: "r", "w", "a","b",...

overwrites!

```
file handle = open("file name", "file mode")
```

#### Read

```
    content = fh.read() reads the whole file in the content string. Good for small and not structured files.
    line = fh.readline() reads the file one line at a time storing it in the string line
    lines = fh.readlines() reads all the lines of the file storing them as a list lines
    using the iterator:
    for line in f: #process the information

which is the most convenient way for big files.
```

#### Write

```
file handle.write(data to be written)
```

```
file_handle.close()
```

# File Input/Output

more info in the Practical6 notes...

```
fh = open("file samples/textFile.txt", "r") #read-only mode
content = fh.read()
print("--- Model (the whole file in a string) ---")
print(content)
fh.close()
print("")
print("--- Mode2 (line by line) ---")
with open("file samples/textFile.txt", "r") as f:
    print("Line1: ", f.readline(), end = "")
    print("Line2: ", f.readline(), end = "")
print("")
print("--- Mode3 (all lines as a list) ---")
with open("file samples/textFile.txt", "r") as f:
    print(f.readlines())
print("")
print("--- Mode4 (as a stream) ---")
with open("file samples/textFile.txt", "r") as f:
    for line in f:
         print(line, end = "")
--- Model (the whole file in a string) ---
Hi everybody.
This is my first file
 and it contains a total of
 four lines!
--- Mode2 (line by line) ---
Linel: Hi everybody,
Line2: This is my first file
 --- Mode3 (all lines as a list) ---
['Hi everybody,\n', 'This is my first file\n', 'and it contains a total of\n', 'four lines!']
 --- Mode4 (as a stream) ---
 Hi everybody,
This is my first file
 and it contains a total of
 four lines!
```

## http://qcbsciprolab2020.readthedocs.io/en/latest/practical6.html

#### Exercises

- 1. Implement a function that takes in input a string representing a DNA sequence and computes its reverse-complement. Take care to reverse complement any character other than (A,T,C,G,a,t,c,g) to N. The function should preserve the case of each letter (i.e. A becomes T, but a becomes I). For simplicity all bases that do not represent nucleotides are converted to a capital N. Hint: create a dictionary revDict with bases as keys and their complements as values. Ex. revDict = ["A": "T", "a": "t", ...].
- 1. Apply the function to the DNA sequence "ATTACATATCATACTATCGCNTTCTAAATA"
- Apply the function to the DNA sequence "acaTTACAtagataATACTaccataGCNTTCTAAATA"
- 3. Apply the function to the DNA sequence "TTTTACCKKKAKTUUUITTTARRRRRAIUTYYA"
- Check that the reverse complement of the reverse complement of the sequence in 1. is exactly as the original sequence.

#### Show/Hide Solution

- 2. Write the following python functions and test them with some parameters of your choice:

  - 2. checkSum: the function has a list and an integer as parameters and returns True if the sum of all elements in the list equals the integer, False otherwise. Example: checkSum([1,2,3], 6) --> True, checkSum([1,2,3],1) --> False.
  - 3. checkPerfect: the function gets an integer as parameter and returns True if the integer is a perfect number, False otherwise. A number is perfect if all its divisors (excluding itself) sum to its value. Example: <a href="https://document.org/reckless-section-number-sect

Use the three implemented functions to write a fourth function:

getFirstNperfects: the function gets an integer N as parameter and returns a dictionary with the first N perfect numbers. The key of the dictionary is the perfect number, while the value of the dictionary is the list of its divisors. Example: | getFirstNperfects(1) --> {6 : [1,2,3]}

Get and print the first 4 perfect numbers and finally test if 33550336 is a perfect number.

WARNING: do not try to find more than 4 perfect numbers as it might take a while!!!
